

Lilac Solutions: sustainable extraction for today's world

September 2023

ELECTRIC VEHICLES REQUIRE 20X GROWTH IN LITHIUM SUPPLY

Automakers Are Going 100% Electric

- \$1.2 trillion to be invested in the EV transition this decade¹
 Lithium is a Primary Bottleneck to the Energy
 Transition
- Lithium supply needs to grow 20x for 100% EV future

Conventional Lithium Production is Failing

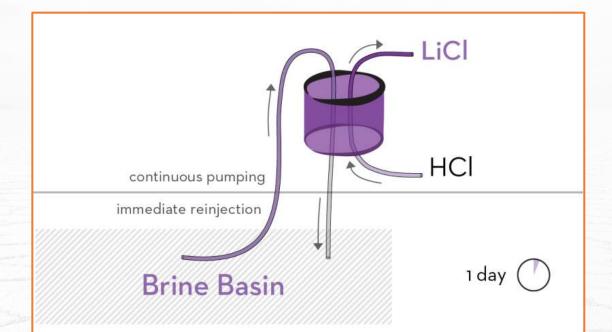

- Hard rock resources are small and will be exhausted quickly
- Brine resources are large but can't scale fast with current tech
 Lilac is Uniquely Positioned to Scale Lithium
 Production
- Our ion exchange technology unlocks and upsizes new production
- World-class team in project development and operations

HOW DOES LILAC'S PROCESS WORK?

- Lilac manufactures our patented IX beads and loads them into IX modules
- Brine (salt water) is pumped from a natural aquifer and through the IX modules where it contacts the IX beads
- IX beads absorb lithium from the brine in minutes, then the brine is returned to the aquifer
- IX beads are treated with acid to produce lithium chloride
- Lithium chloride is processed through conventional "downstream" methods to produce finished lithium carbonate or lithium hydroxide products for battery manufacturers

LILAC SOLVES THE LITHIUM INDUSTRY'S CRITICAL PROBLEMS

Unlock New Sites

- South America has only 4 brine projects in production; all these projects feature brines with high lithium grades, yet they struggle to expand due to problems with technology and environmental impact
- South America has dozens of large, undeveloped project sites, but most of these sites have lithium concentrations that are 2-10x lower than existing production; US and EU also have dozens of potential project sites, but lithium concentrations are 4-20x lower than existing production
- For low grade brines, Lilac is uniquely capable of bringing these projects into production; for medium and highgrade brines, Lilac is uniquely capable of realizing the full potential of these project sites with large production rates

Accelerate Development Time

- Battery factories are built in 2 years while conventional brine projects take 10 years due to sprawling footprint and slow commissioning
- Lilac can bring a brine project fully online in 4 years due to faster commissioning and processing than conventional projects

Increase Production Rate

- Conventional brine projects produce just 0.1% of their resource per year due to constraints on land and water
- Lilac needs less land and less water, enabling up to 10x higher production rate

LILAC SOLUTIONS: SUSTAINABLE EXTRACTION FOR TODAY'S WORLD

Proven Technology and Operations

- Rigorous testing with 200,000 hours of continuous operation on 60+ brines at bench, mini-pilot, and pilot scale
- Water consumption: 2-10 ton_H2O/ton_LCE
- Successful pilot plant at a remote project site in Catamarca, Argentina, achieved 24/7 continuous operations within one month, and delivered first truckload of lithium chloride ahead of schedule
- Completed mechanical testing of commercial scale IX vessel, validating FEL-3 engineering, ready for FID and FEED
- Diversified project portfolio in partnership with the world's largest resource owners in different continents

Top Tier Global Investors + Federal Grant

- \$248 million private capital raised to date. Selected for \$50 million grant by U.S. Department of Energy
- 250+ employees. Offices in the US, Canada, Chile, Argentina, Bolivia and UK

LOWERCARB capital

FEL-1 Testing

PROJECT DEVELOPMENT AND ASSESSMENT PROCESS

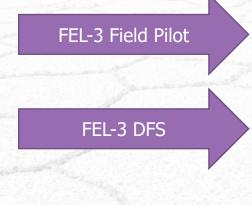

Airfreighted quantities of brine for assay and initial recovery profile and reagent initial use.

FEL-2 Mini-Pilot

FEL-2 PFS

~20,000 L of Brine for extended testing, optimization of extraction method, establishing operating conditions, reagent use and resin life. Allows sufficient data for Pilot plant design.

Development of the scope of the project, trade off studies for configuration options, overall project flowsheet, CAPEX/OPEX and economic analysis. Sufficient definition to support Environmental Permit application

10-50 ton per year LCE production on site to produce concentrated LiCl . 3-6 month duration to validate technology application for a specific site and produce data for Feasibility Study/FEL-3.

Process flowsheet frozen, design progressed to develop Class 3 estimate, execution plan and contracting strategy with risk assessment to support Final Investment Decision

Project Execution

Detailed engineering, procurement and construction of DLE modules and balance of plant.

CHALLENGES FOR CHILE AND DLE

- Lithium in Chile: We are in a race against time
- Chile needs a clear regulatory path with a wider agreement
- Clear rules for capital intensive projects
- Improvement of permitting management and approvals
- Licencia Social: demonstrating to the communities that sustainable projects with minimal negative impacts and significant positive impacts can be carried out through direct extraction
- Reinjection, as the method that will allow mitigating impacts and improve efficiency on the surface, in the water balance of the basins and the production
